ML Week 0x01 Introduction

Some preliminaries

- English
- This is an introduction. There's so much more.
- None of this gives quick fixes. Some is quicker than others.
- The goal is to play with data.
- We have to learn scikit-learn, even if it's not what you use later.

What is ML?

1. Some algorithms we know how to write
   (a) Sort numbers
   (b) Fly a plane
2. Some algorithms we don't know how to write (example: drive a car)
   (a) Drive a car
   (b) Read addresses on envelopes
   (c) Detect spam
3. Maybe we can write programs to write programs when we can't
4. Some things we used to say
   - Artificial intelligence
   - Expert systems

Types of ML

1. Supervised
   (a) Training data: input and correct responses
   (b) Regression (continuous) (example: home prices)
   (c) Classification (discrete) (example: medical outcome (alive/dead))

2. Unsupervised
   (a) Clustering
   (b) Deep neural networks
   (c) Associative (example: human experience, e.g. from a career)
   (d) Dimensionality reduction
3. Reinforcement
   (a) Make a choice, get feedback
   (b) Online
   (c) Can be stochastic (example: predicting weather from local clues)

Curse of Dimensionality

1. *Fléau (ou : malédiction) de la dimension*
2. Volume of unit cube $\pm\epsilon$
3. Distance from $(0, 0, \ldots, 0)$ to $(1, 1, \ldots, 1)$
4. Physics: $1/r^{d-1}$
5. It's easy to get lost...
6. Richard Ernest Bellman, Dynamic programming, Princeton University Press, 1957.

Probability

1. Event
2. Complement of an event
3. Disjoint (mutually exclusive)
4. Independent events — knowing one outcome gives no information about other
5. addition ($\times 2$), multiplication $\times 2$)
6. Conditional probability
7. Marginal probability
8. Joint probability

Statistics

1. Goal for a bit: think like a statistician
2. What is statistics? ($\times 3$)
3. Said differently: goal is to compare reality to a model
4. Or to find a model and then compare.
5. Good statistical models are often relatively simple.
6. What is data science ($\times 5$)

Study design

1. Anecdote
2. Study types ($\times 2$)
3. Observational studies can't conclude causality
4. Observational studies can be
   - prospective: identify individuals, collect information
   - retrospective
   - we can combine them
5. Experimental studies
   - We do stuff
   - Can conclude causation if properly designed
     - controlling: hold other variables constant (e.g., drink pill with full glass of water even if we don't care)
     - randomization: cancel out effects we can't control
     - replication: enough participants
6. Study types example
   - Sunscreen use correlated to skin cancer rates.
   - Confounding variable
7. Random sampling hazards
   - Not actually random

- Convenience sample
- Non-response bias

Statistical concepts

1. Variable types
   - Input: Features
   - Input variables measure: Explanatory variable
   - Output: Response variable
   - Training set
   - Test set (tune parameters) (compare model parameters)
   - Validation set (tune hyperparameters) (measure performance of model)
   - Cross validation
   - Bias - same errors regardless of input (inflexible)
   - Variance - different errors with same input (too flexible)
2. Population statistics ($\times 6$)
   - sample mean vs population mean ($\times 7$)
   - Sample standard deviation and variance: divide by $n - 1$
3. Distributions
   - Important: pdf (pmf), cdf, ppf ($\times 5$)
     - pdf = densité de probabilité
     - pmf = fonction de masse
     - cdf = fonction de répartition
     - ppf = ?
   - The rest: just so you've heard of them
   - Boxplot ($\times 2$)
4. Normal distributions ($\times 2$) — TODO: compare in matplotlib, quantile-quantile plot
   - Sample mean vs population mean
   - How close are they?
   - Point estimate: if you have to guess, this is it
   - Correction: if I want to be on average weighted right as much possible

5. Sampling distributions ($\times 3$)

   - Sampling mean is unimodal and approximately symmetric
   - It is centred at population mean.
   - The standard deviation of the sample mean tells us how far a point sample's mean is likely to be from the population mean. In other words, how much error we are likely to have in the point estimate's mean. **Standard error.**
   - TODO: Generate uniform population, sample, and plot sampling distribution
   - TODO Generate highly skewed population, sample, and plot sampling distribution
   - In real life, we don't have access to the population parameters. We have to *estimate* them from samples. So we can't *know* the standard error (erreur type).

6. Confidence intervals ($\times 3$)

   - Sampling is usually expensive.
   - Reminder: Independent random samples!
   - Correct language: "We are 95% confident that the population parameter is between..."
   - Incorrect language: describe the confidence interval as capturing the population parameter with a certain probability.
   - This is one of the most common errors: while it might be useful to think of it as a probability, the confidence level only quantifies how plausible it is that the parameter is in the interval.
   - Another especially important consideration of confidence intervals is that they only try to capture the population parameter. Our intervals say *nothing* about the confidence of
     - capturing individual observations
     - a proportion of the observations
     - about capturing point estimates

     Confidence intervals only attempt to capture population parameters.
